How is the Angular project structure different from that of the Express HTML customer-facing page?

The main difference between Angular and Express is that the Angular project structure is primarily designed for the frontend while Express is designed for the backend of the customer-facing webpage (Dhaduk, 2021). Also, Angular is used by fewer websites, although it is considered ideal for websites that receive large amounts of traffic; Express, on the other hand, is very popular due to it not having a strict framework and being very easy to develop with.

What are some advantages and disadvantages of the SPA functionality?

Some advantages of a single-page application (SPA) include high speed and quick responsiveness, reduced server workload, cross-platform compatibility, and improved user experience. Some disadvantages of a SPA include increased vulnerability to cybersecurity breaches, issues with Search Engine Optimization (SEO), and complex development requirements.

What is the process of testing to make sure the SPA is working with the API to GET and PUT data in the database?

The process of testing the SPA and API functionality involves several steps. First, one has to complete unit testing to ensure that every component of the web application is working as intended individually. This would include verifying the functionality of the API endpoints and checking the frontend and backend of the SPA. Then, one will need to complete integration testing to check how all of the webpage components work together. This form of testing involves checking the website's exception handling and verifying that the SPA can correctly trigger API calls and send the right output back to the user.
